Objective:

Set up a robust backend that connects with Yahoo's finance APIs on RapidApi as given below.

1. [Get analysis](#)
2. [Get news](#)

The backend you build should have 2 endpoints (1 for each of the above) each of these takes the symbol as a query param

Guidelines:

1. Write well structured code that is readable, uses proper naming conventions and is efficient
2. Leverage any 3rd party library / software if you think it is necessary
3. Set up your own RapiAPI account keys (doesn't cost any money)
4. Think of ways of how to make the APIs blazing fast (and implement it) (< 1 sec response)
5. Please set up a github repository and share it with North Loop once you're done - we should be able to clone it, npm i and then run without any hassle
6. You can ask clarifying questions over email, if needed
